# **Increasing the Reliability of Geological Models Using Spectral Decomposition and Seismic Facies Analysis**

H. Yadav (ffA), V. Cybulskij\* (ffA) & G. Paton (ffA (Foster Findlay Associates Ltd))

# Dataset

3D Seismic volume from NW Australia, Exmouth Sub-basin.

- Stybarrow Oil Field with four wells.
- Eskdale Oil Field with two wells.

**Limited well data availability is a typical situation for majority of exploration scenarios.**

# The technical challenge

## How to rapidly reproduce subsurface complexity in geological model?

Traditional approaches:

- Statistical modelling;
- Object modelling.

Geological Expression approach:

- Reveal intra channel heterogeneity;
- Constrain channel geometry;
- Classify internal heterogeneity.

# The solution

Kriging

Sequential Indicator Simulation

Shape Modelling

Using Geological Expression workflows

Spatially accurate facies to drive distribution of well logs

# Workflow overview

Structural analysis

Fault interpretation

Frequency decomposition

Geobody interpretation

Facies interpretation

Integration

Geocellular Model

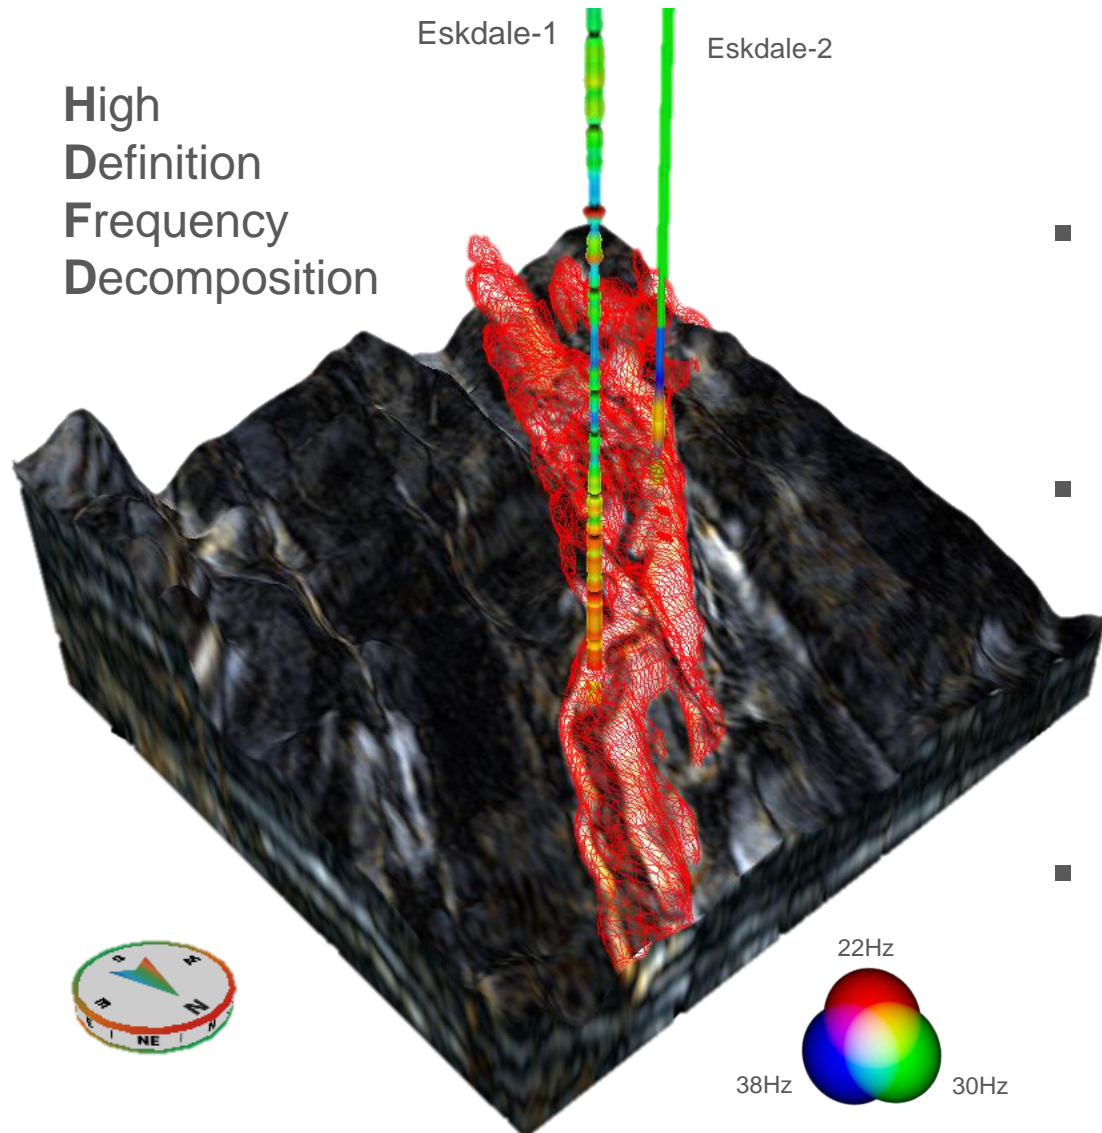

Property distribution

# Structural analysis

- SO Semblance, Dip and Tensor edge attributes were used for complex fault analysis;
- CMY blends of 3 edge attributes shows the complete fault network;
- As a result detailed fault system was interpreted and implemented in to Eksdale geological model.

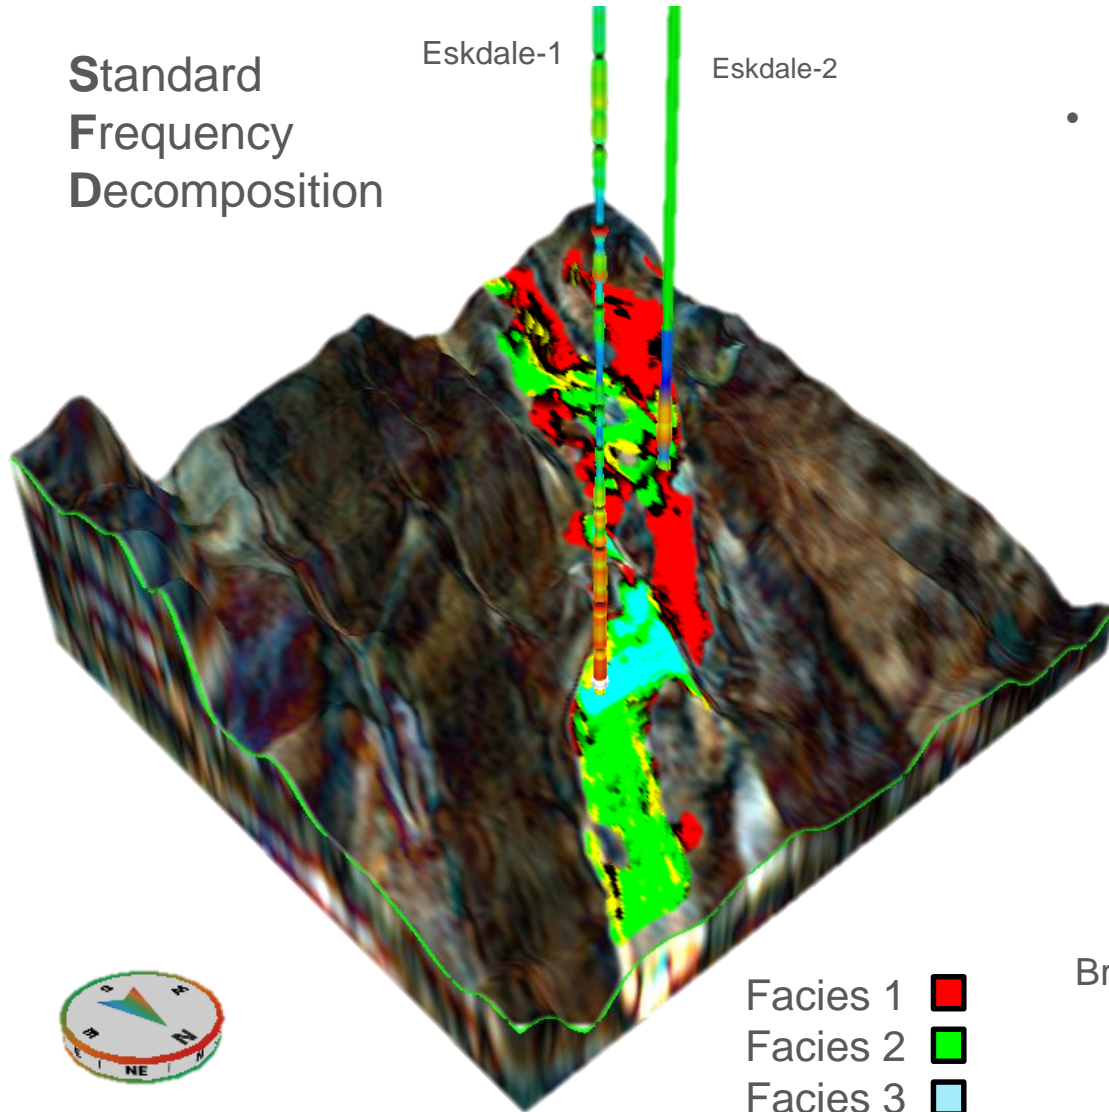

# Adaptive Geobodies Interpretation

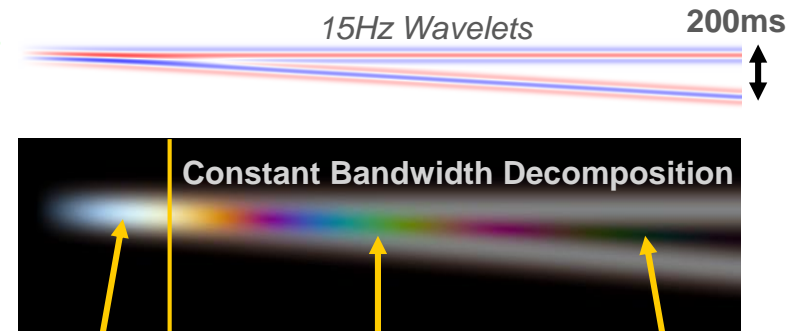

- Adaptive Geobodies were used to track the channel directly from the RGB blend;
- Manual manipulation of the geobody surface ensured the interpreted geobody matched the data and was geologically meaningful;
- The geobody was used as a container to describe the extents of the channel system.

# Facies Classification

Standard  
Frequency  
Decomposition

- Interactive Facies Classification (IFC+) enabled a multi-attribute classification of the RGB blend constrained by the Adaptive Geobody which delineated the different facies in the reservoir.

Brightest at tuning

No interference

Layer of spectral interference shown as color variation with thickness – occurs above tuning

## Geocellular model

Geocellular  
model

Property model

- The IFC+ classification volume was imported into the model maintaining the discrete facies descriptions;
- This gave the ability to rapidly build facies models with limited well data.

# Summary

- Multi-attribute seismic colour blends **reveal** the geometries and depositional facies in the data;
- This information can be **rapidly** brought into the reservoir model and used to propagate petrophysical information **accurately** away from the well location;
- The workflow enable us to produce geological aesthetics model of subsurface features.

**Thank you for  
attention**
